

# Operational Use of Air Quality Numerical Forecast Model Guidance

William Ryan

Michelle Palmer

Department of Meteorology

The Pennsylvania State University

International Workshop on Air Quality Forecasting Research

Boulder, CO December, 2009

# What Do We Forecast?

12Z 25H-48H 2 day 8h max sf O<sub>3</sub> (ppb) Valid 10 AUG 2009

Forecasts are verified by peak 8-hour averaged O<sub>3</sub> at location of state and local monitors

While model forecast location of peak O<sub>3</sub> is of interest, air quality alert applies to entire metropolitan area in order to reduce emissions as well as protect health

# Complex Land-Sea Boundary Effects

(prd) 12Z 25H-48H 2 day 8h max sf O3 (ppb) Valid 05 AUG 2009

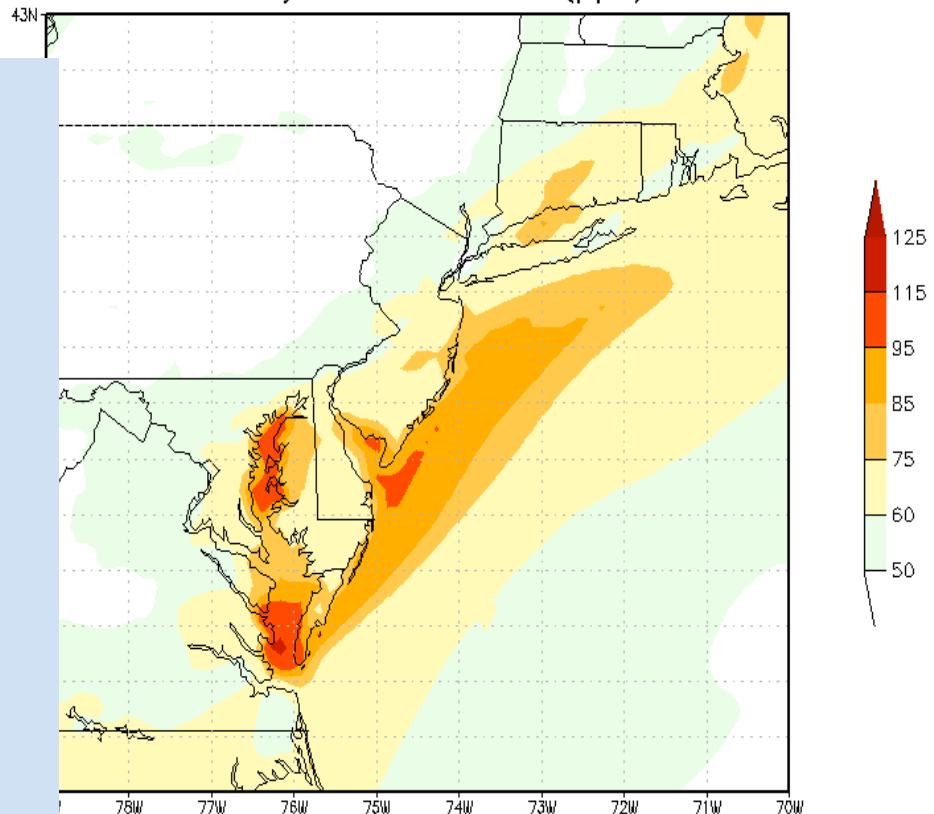

Numerical O<sub>3</sub> models (NAQC shown at right) often forecast high O<sub>3</sub> along land-sea boundaries.

These areas of high concentrations can “bleed” inland.

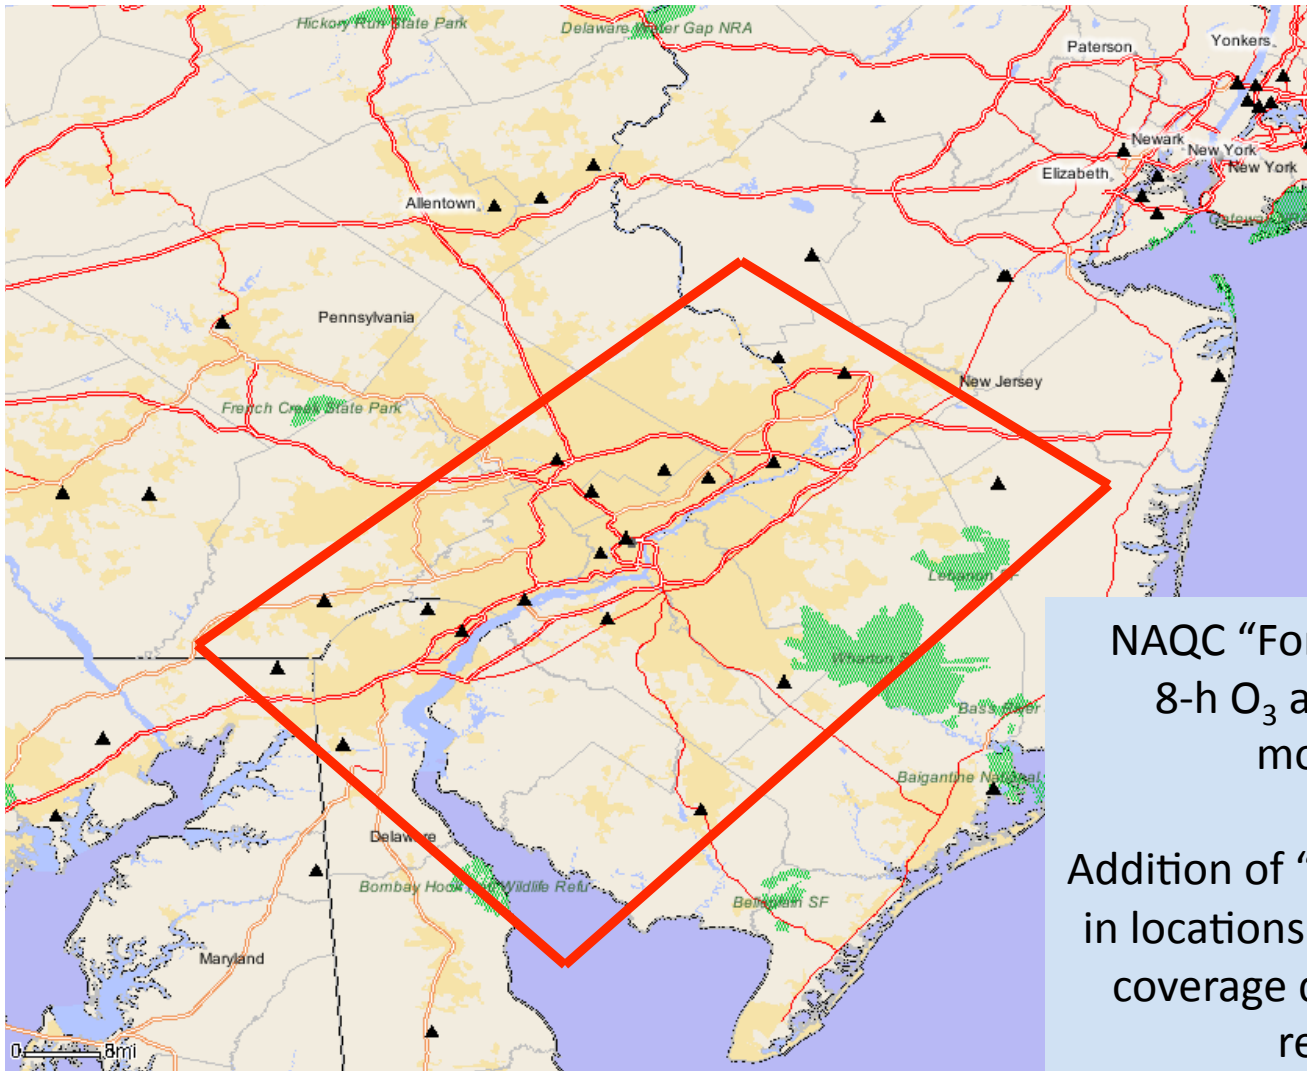

## First Order Post-Processing:

Restrict domain peak O<sub>3</sub> guidance to location of monitors.

Can retrieve “point” data quickly from [www/weather.gov/aq](http://www.weather.gov/aq) using Firefox

# Philadelphia O<sub>3</sub> Monitor Network (2007-2009)

NAQC "Forecast" is peak 8-h O<sub>3</sub> at location of monitors.

Addition of "proxy" monitors in locations with less dense coverage does not affect results.

# Numerical Forecast Model Guidance: NAQC Model Changes During Period of Interest

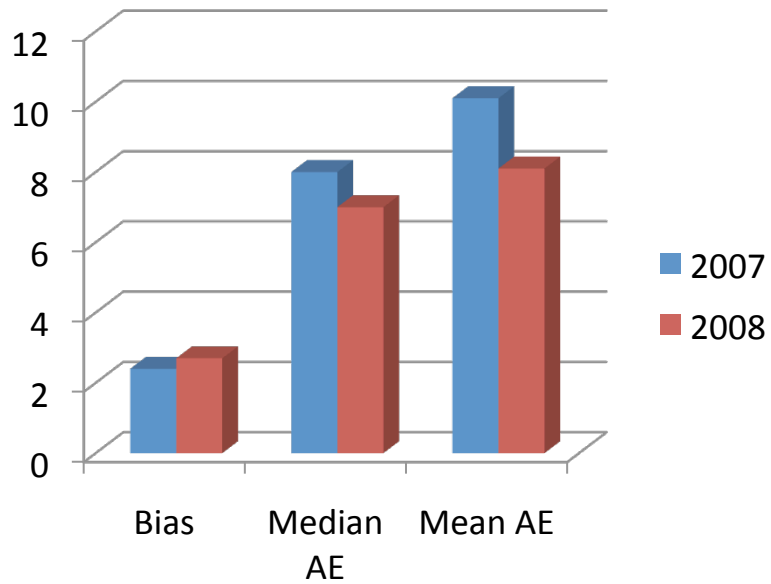

Emissions Updated Yearly (May)

NAQC Upgrade : Sept, 2007 (Experimental → Operational)  
BC, ACM PBL, NAM photolysis

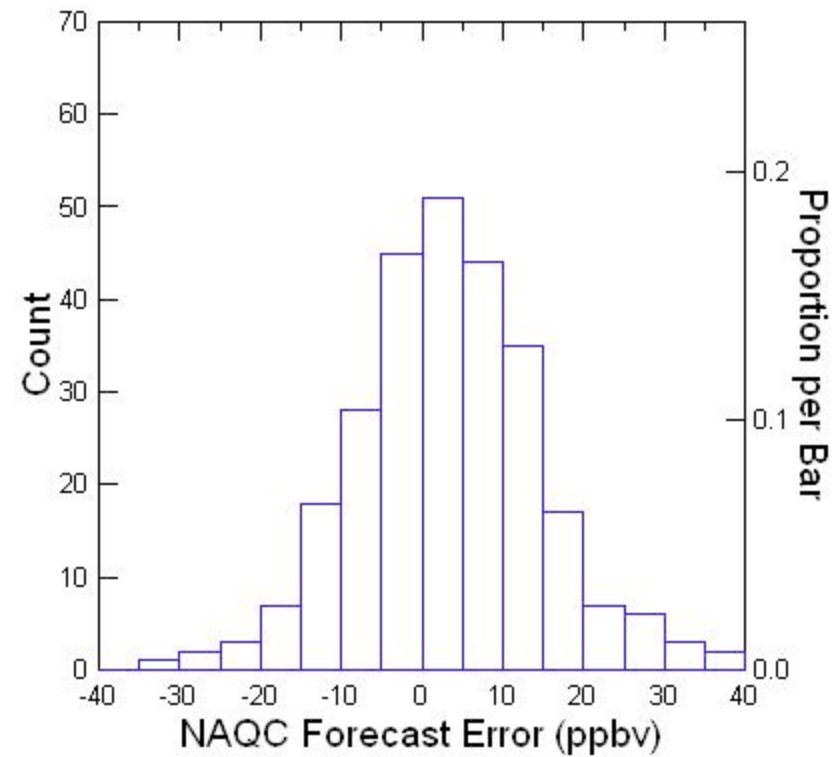

NAM Upgrade: Mar, 2008 (horizontal advection, AIRS radiance, soil moisture)

NAM Upgrade: Dec, 2008 (GDAS, absorption coefficient water, ice)

# NAQC Forecast Skill in PHL 2007-2008

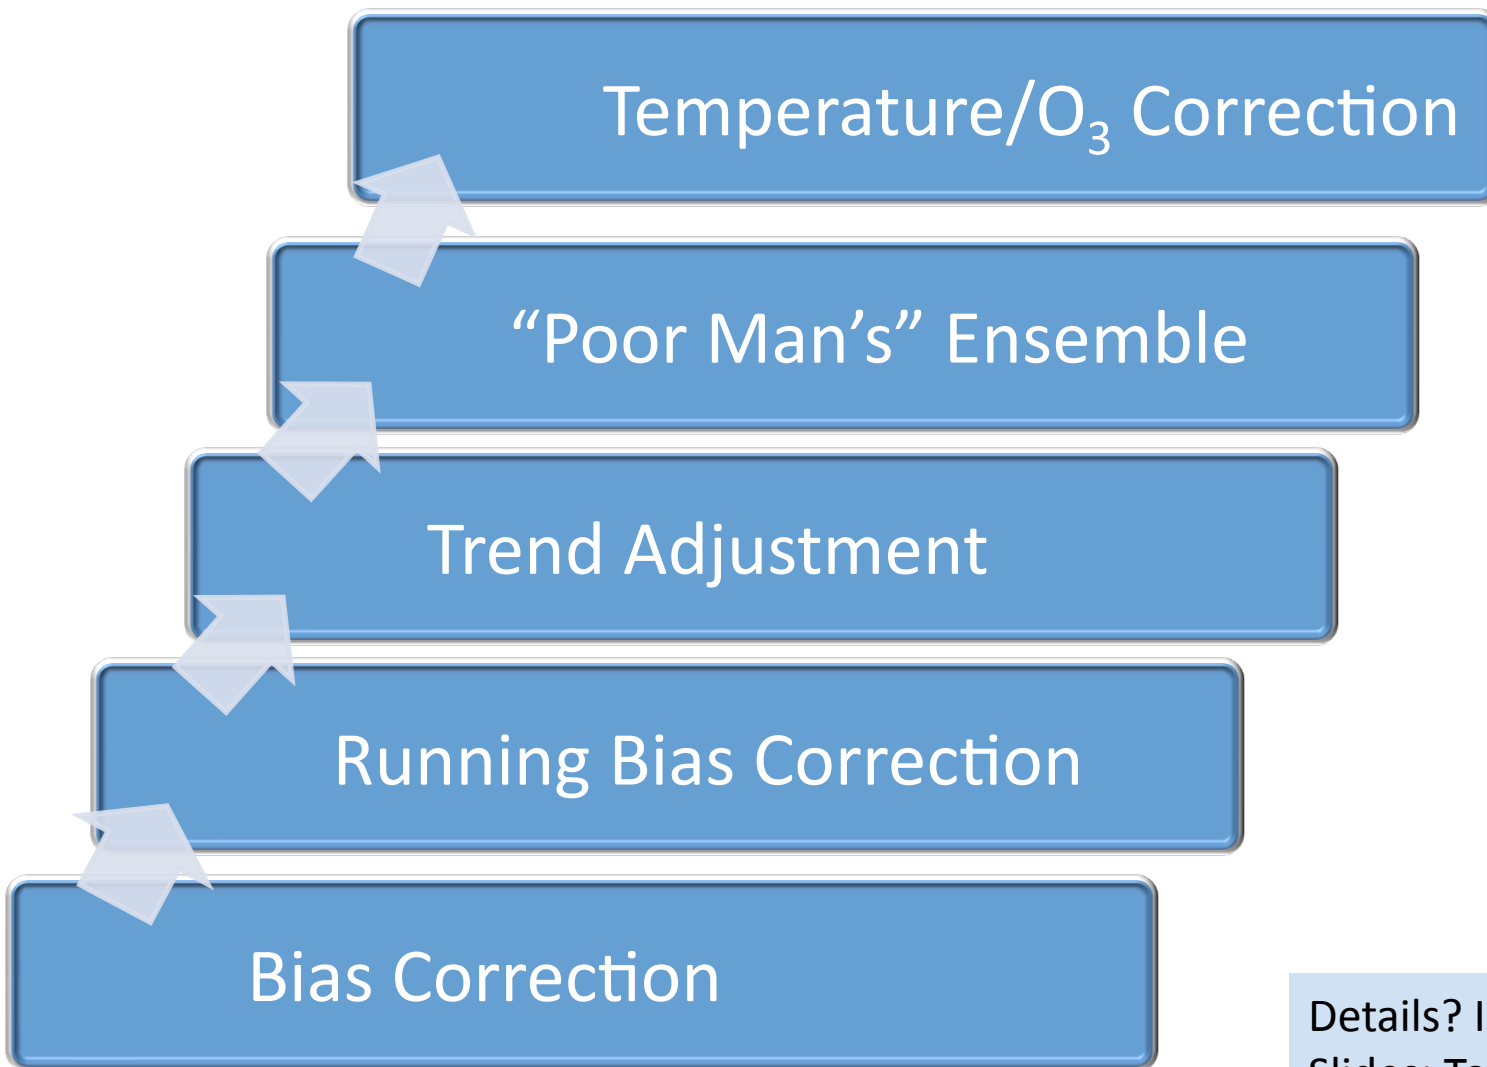

PHL NAQC Forecasts		
	r	r <sup>2</sup>
2007	0.76	0.58
2008	0.76	0.58

NAQC Forecast Error for PHL Area (2007-2008)

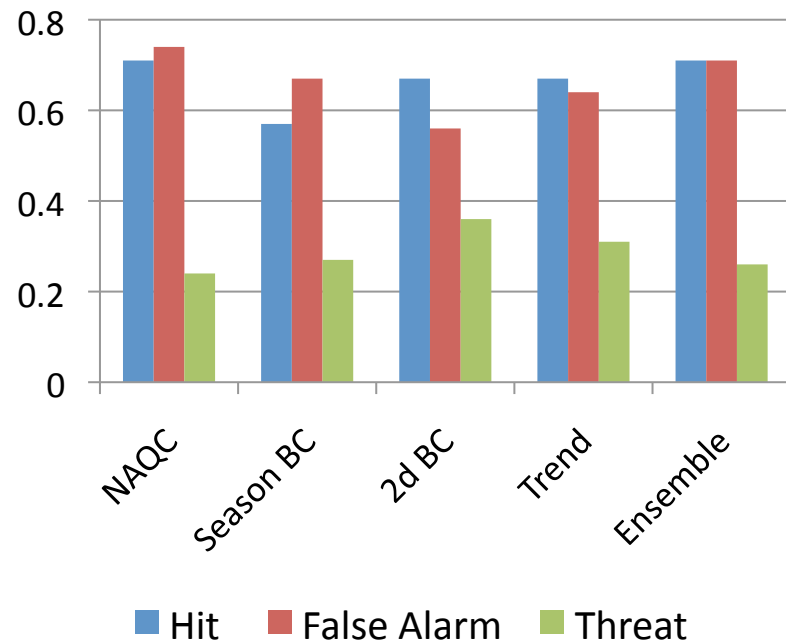

# Ladder of Simple Post Processing in the Operational Environment

Details? In-Depth  
Slides: Topic 1

# Results of Bias, Trend and Ensemble Methods

- All methods showed slight improvement in overall skill. Bias removed, mean absolute error improvement from 0-9%.
- 2-Day Running Bias Correction reduced False Alarms with only slight reduction of the Hit Rate.
- NB: 2009 may be an anomalous O<sub>3</sub> season (In Depth Slides: Topic 2)

# Temperature and NAQC Forecast Guidance

Peak  $O_3$  concentrations, either forecast or observed, are correlated to  $T_{\max}$ .

NAQC forecasts (2009 shown left) appear to be sensitive at  $T_{\max} > 82^\circ\text{F}$

Evidence of decoupling of  $T_{\max}$ - $O_3$  association in recent years?

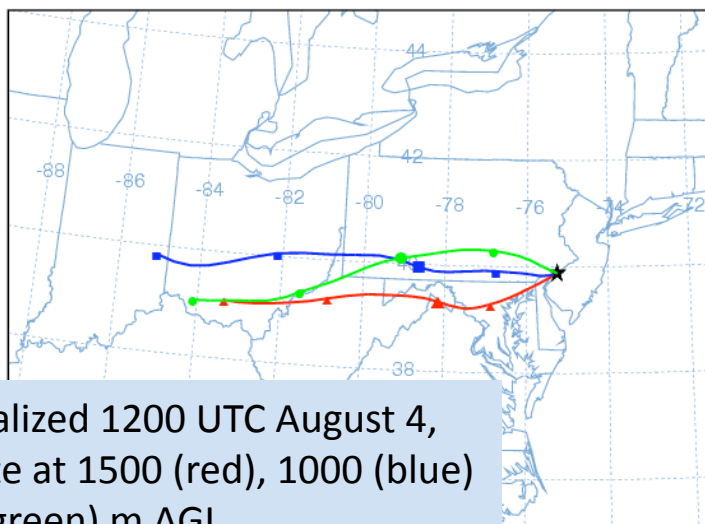

**In-Depth Slides: Topic 3**

and 500 (green) m AGL.

Hourly O<sub>3</sub> in  
PHL on August 5  
Peak 8-h Ave: 69 ppbv

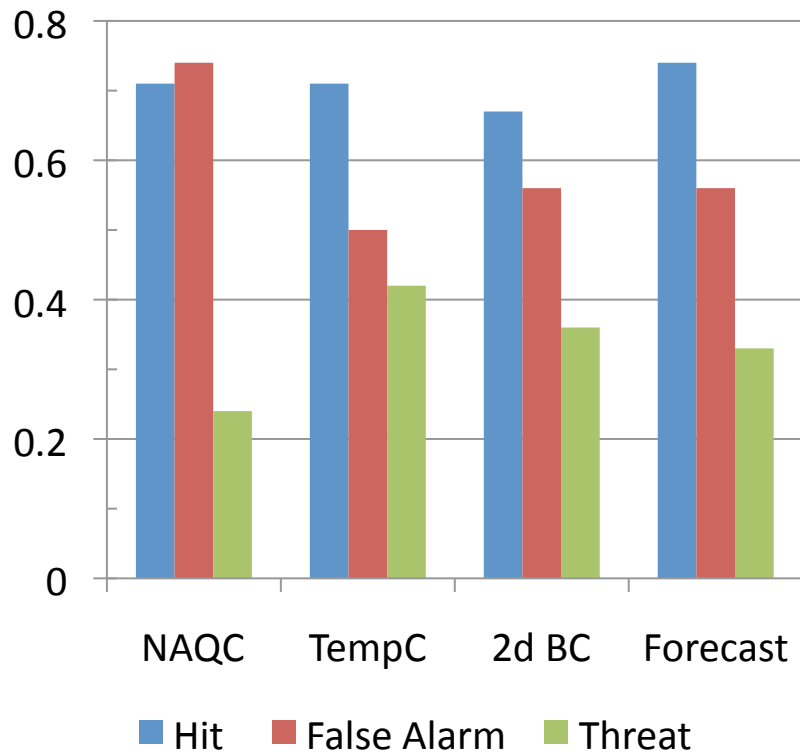

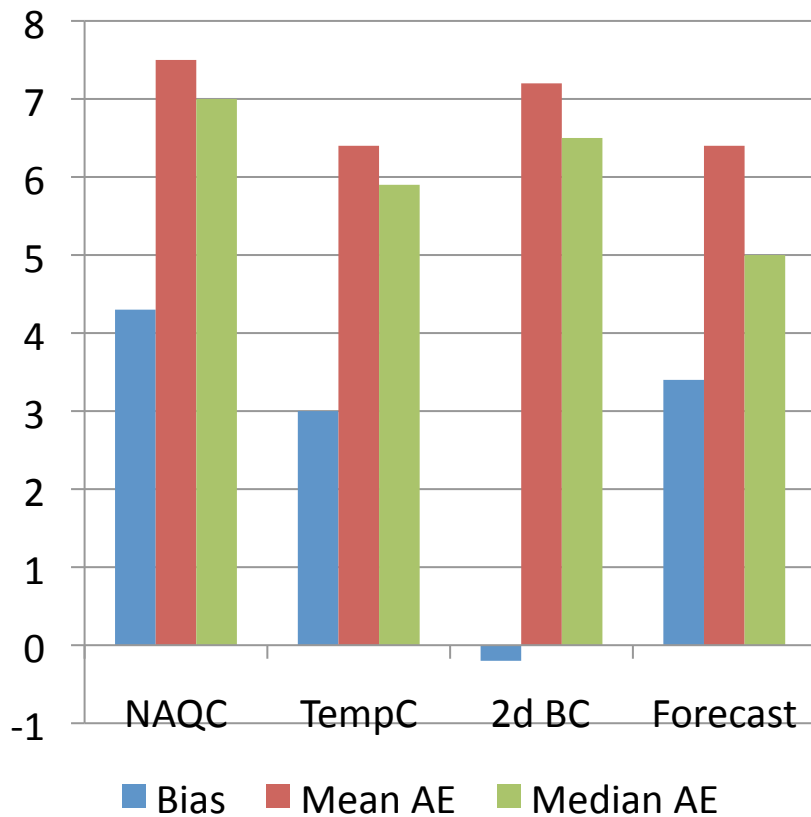

# Temperature and Persistence Adjustment

- Fit regression model with observed  $O_3$  (2007-2008) as predicand,  $T_{\max}$ , persistence  $O_3$  and NAQC forecast  $O_3$  as predictors.
- Modest improvement overall but **large reduction** in false alarms with only minor reduction in hit rate.

Details? In-Depth Slides: Topic 4

# 2009 Results

“NAQC” is uncorrected model forecast, “TempC” is temperature and persistent adjusted forecast, “2dBC” is running two-day bias correction, “Forecast” is expert forecast issued to public.

# Summary

- Metric of interest to forecasters is peak domain wide  $O_3$  and particularly at the threshold of 76 ppbv (Code Orange).
- Numerical model forecasts in PHL are skillful but suffer from over-prediction at the Code Orange threshold.
- Overall forecast skill is improved by running bias corrections.
- Skill at Code Orange threshold improved by excluding coastal regions and correcting for temperature and persistence  $O_3$ .
- Another year of data is necessary to fully test these conclusions due to unusual circumstances in 2009.

# Acknowledgements

- Air quality forecasting and research in the Philadelphia Metropolitan area is supported by the Delaware Valley Regional Planning Commission ([www.dvrpc.org](http://www.dvrpc.org)) and the States of PA, NJ and DE.
- Additional research support was provided by the Air and Radiation Management Administration of the Maryland Department of the Environment (<http://www.mde.state.md.us>).

## In Depth Slides

- Topic 2: Comments on the 2009 Ozone Season in the mid-Atlantic
- Topic 3: Temperature-Ozone Relationship Following the NO<sub>x</sub> SIP Rule Implementation
- Topic 4: Using Temperature and Persistence O<sub>3</sub> to Adjust NAQC Forecasts

# In Depth Slides: Topic 1

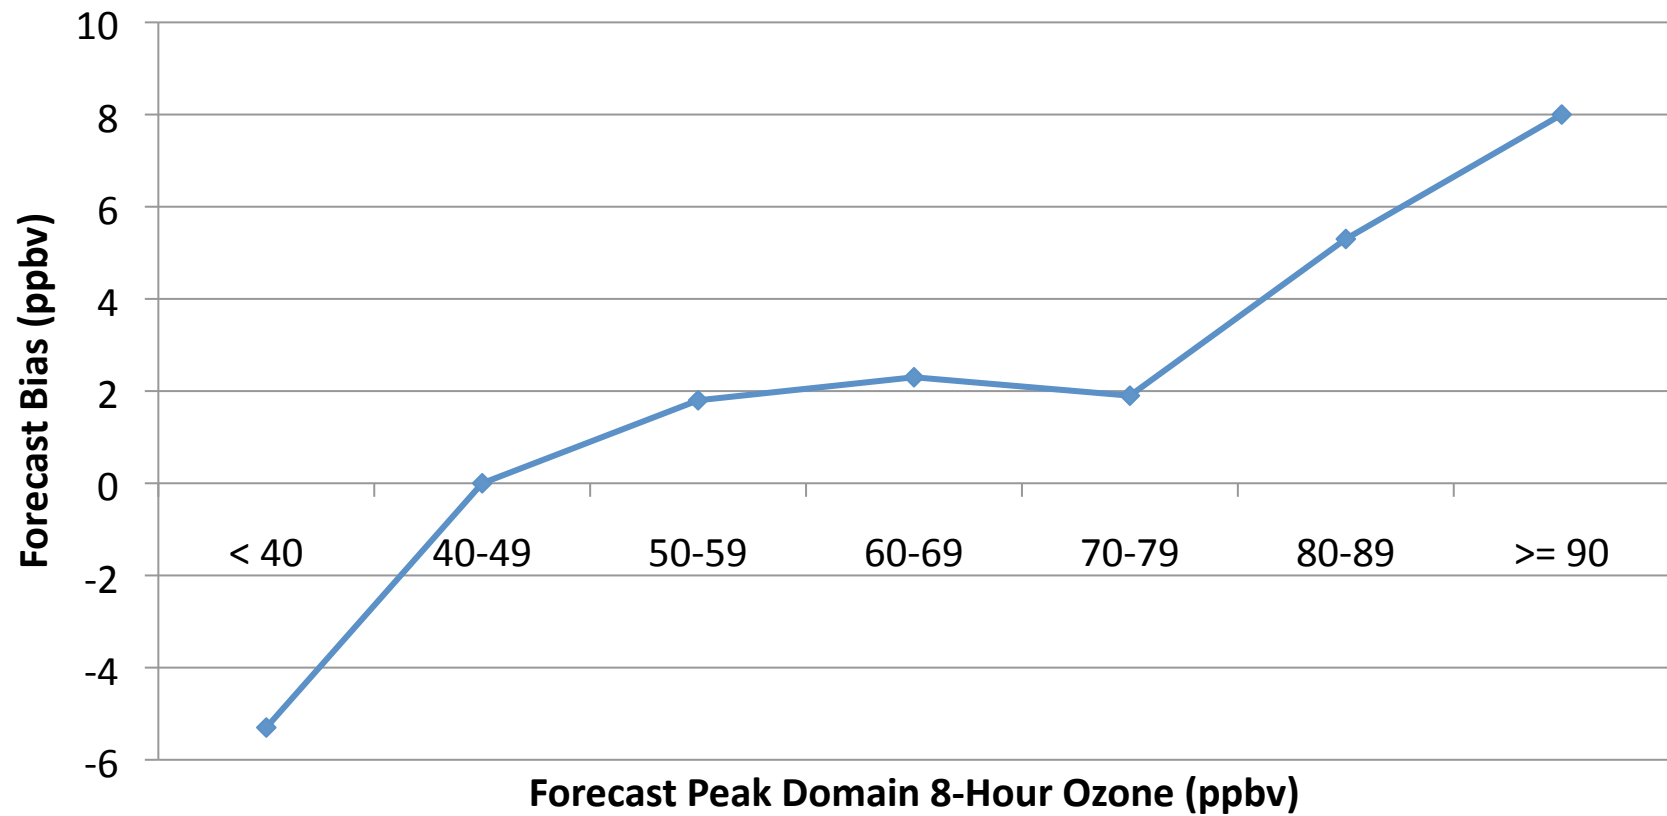

## Post-Processing of Numerical Guidance

- Simple bias correction (BC)
  - Bin forecasts by concentration and correct for historical bias in those ranges.
- Running bias correction (RBC)
  - 2 day running bias correction.
- Trend correction
  - Add recent trend in forecast  $O_3$  to current day observed  $O_3$
- Blend with statistical models
  - “Poor Man’s Ensemble”
- Statistical post-processing
  - Predictors: Forecast, temperature and persistence  $O_3$

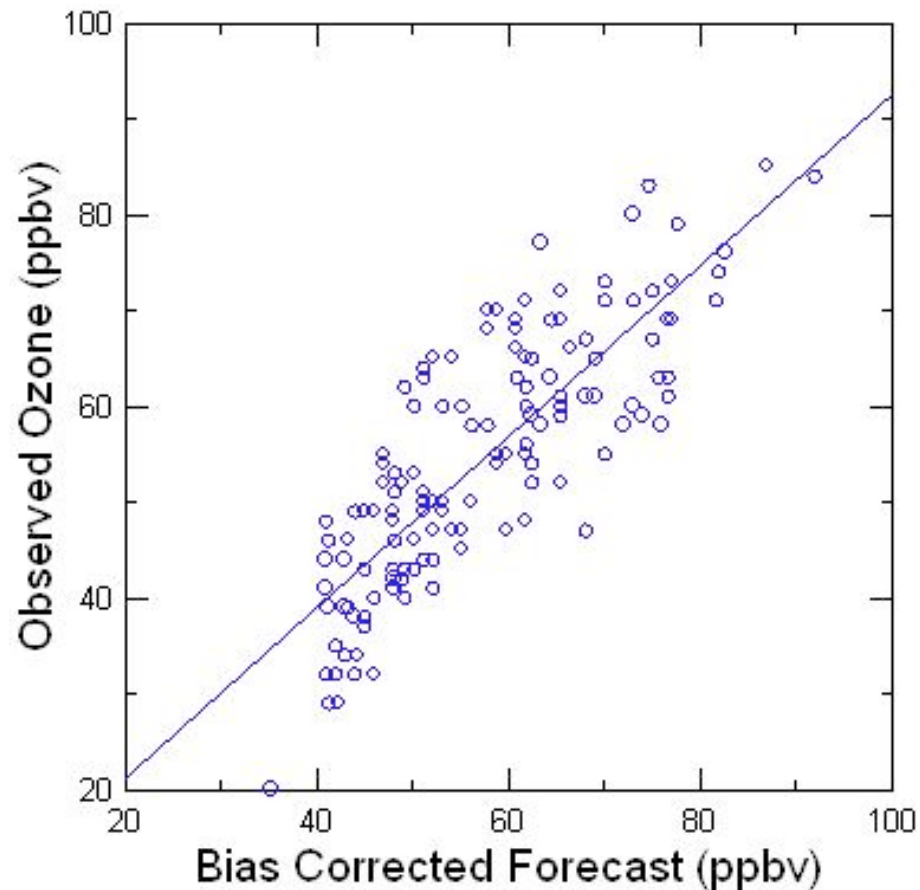

# Simple Bias Correction Applied to 2009

NAQC Forecast Bias (2007-2008)

## 2009 Bias Corrected Forecasts

$N = 143$

$r = 0.82$

$r^2 = 0.67$

$$[O_3] = 3.52 + 0.89*[O_3]_{BC}$$

Overall absolute error similar to uncorrected forecast. No improvement in higher end of observed  $O_3$  distribution.

## Running Bias Correction (Two Day)

- $RB O_3 = f_{d+1} - [((f_{d0} - obs_{d0}) + (f_{d-1} - obs_{d-1}))/2]$
- Current day ( $d_0$ )  $O_3$  must be estimated from early afternoon observations.
- Running bias correction is the average forecast bias over two days preceding the forecast day.
- “f” is peak 8-hour  $O_3$  forecast at monitor locations by the NAQC model. “obs” is observed peak 8-hour  $O_3$  from same locations.

# Two-Day Running Bias Correction

**2007-2009**

N = 406

r = 0.80

r<sup>2</sup> = 0.64

$$[O_3] = 14.4 + 0.76 * [O_3]_{2dBias}$$

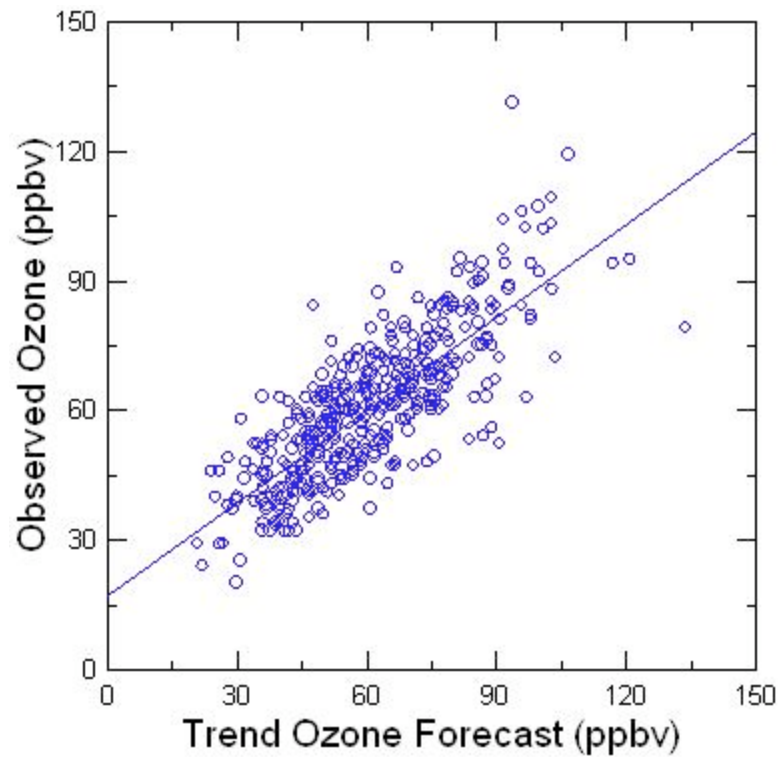

Overall, little change in absolute error from NAQC. Some improvement in bias.

In 75<sup>th</sup>ile (> 65 ppbv), slight degradation in absolute error.

## Trend Correction

- Trend Corrected  $O_3 = (\text{obs}_{d_0} + [\text{fc}_{d+1} - \text{fc}_{d_0}])$ 
  - Today's Peak  $O_3 + [\text{Tomorrow's Forecast } O_3 - \text{Yesterday's Forecast } O_3 \text{ for Today}]$
- Shortcoming: Forecast is issued before today's peak observed  $O_3$  is known.
- Current day forecast from either 0600 or 1200 UTC NAQC runs have not proven reliable so current day peak is typically extrapolated from early afternoon  $O_3$  observations.

# Trend Correction Results (2007-2009)

**2007-2009**

N = 409

r = 0.79

r<sup>2</sup> = 0.62

$$[O_3] = 17.2 + 0.72 * [O_3]_{\text{Trend}}$$

Overall, little improvement to  
NAQC forecast.

## Blend of Statistical and Numerical Models

- Statistical models typically use meteorological, seasonal and persistence predictors to forecast peak domain-wide  $O_3$ .
- These models are simple and cost-effective and have historically provided reasonably accurate forecast guidance.
- Statistical models require relatively long training data sets. Usually 5 or more summer seasons of data.
- Significant changes in regional scale  $NO_x$  emissions beginning in 2002 due to the “ $NO_x$  SIP Rule” have had an impact on the skill of statistical models that are “tuned” to earlier years.

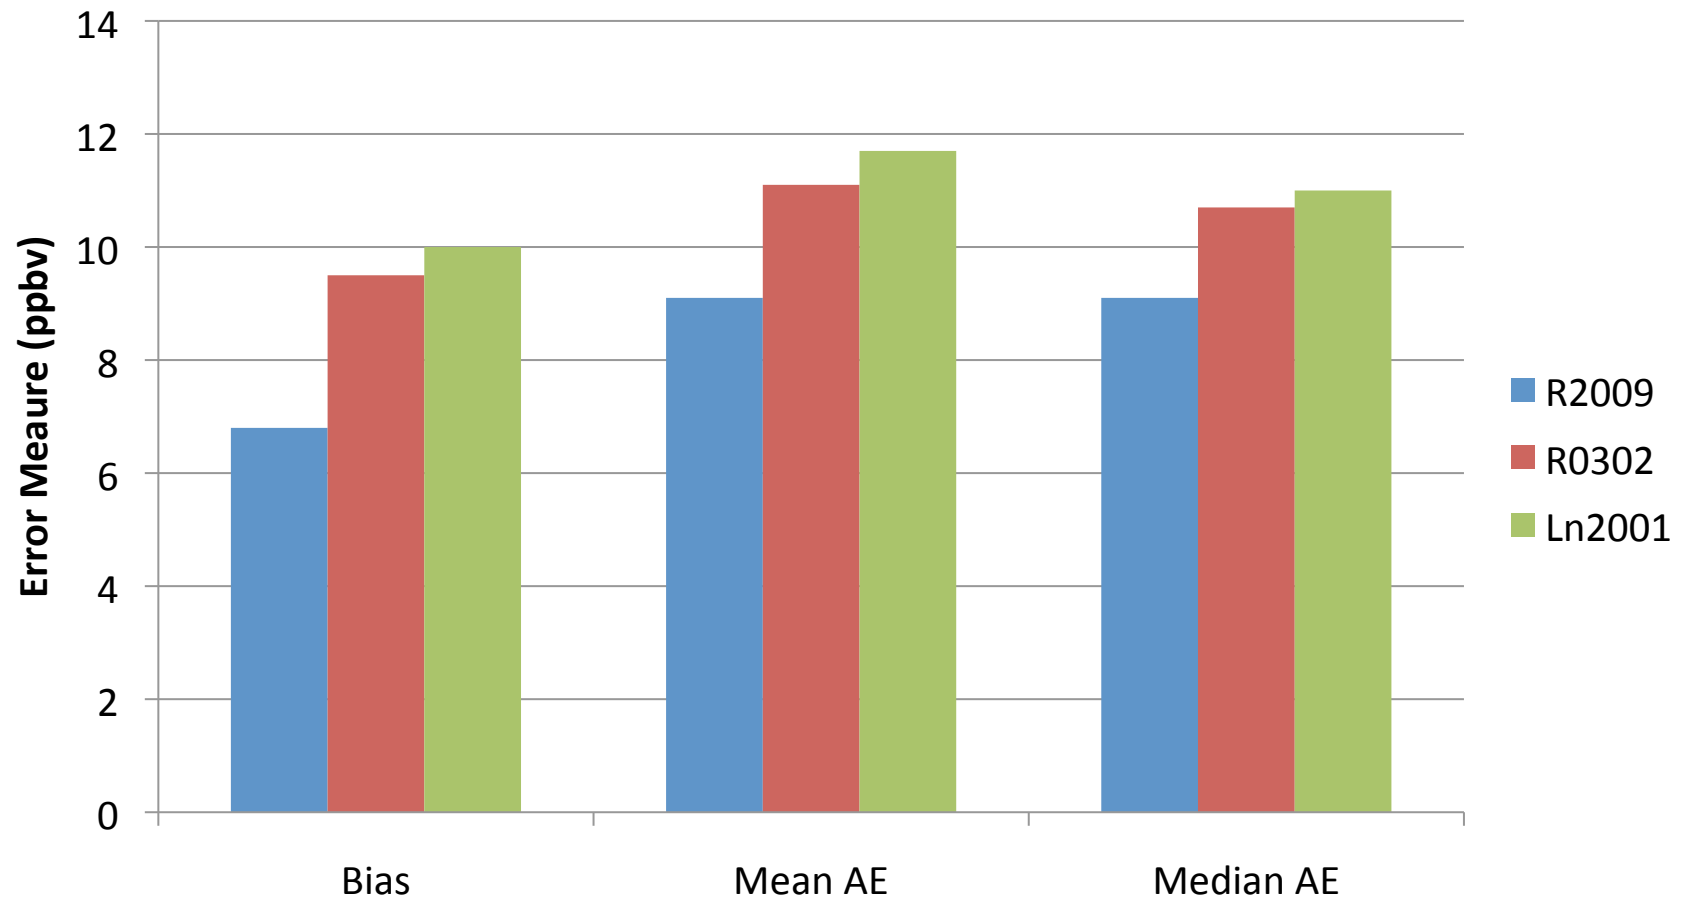

## Statistical Model Bias (2003-2009)

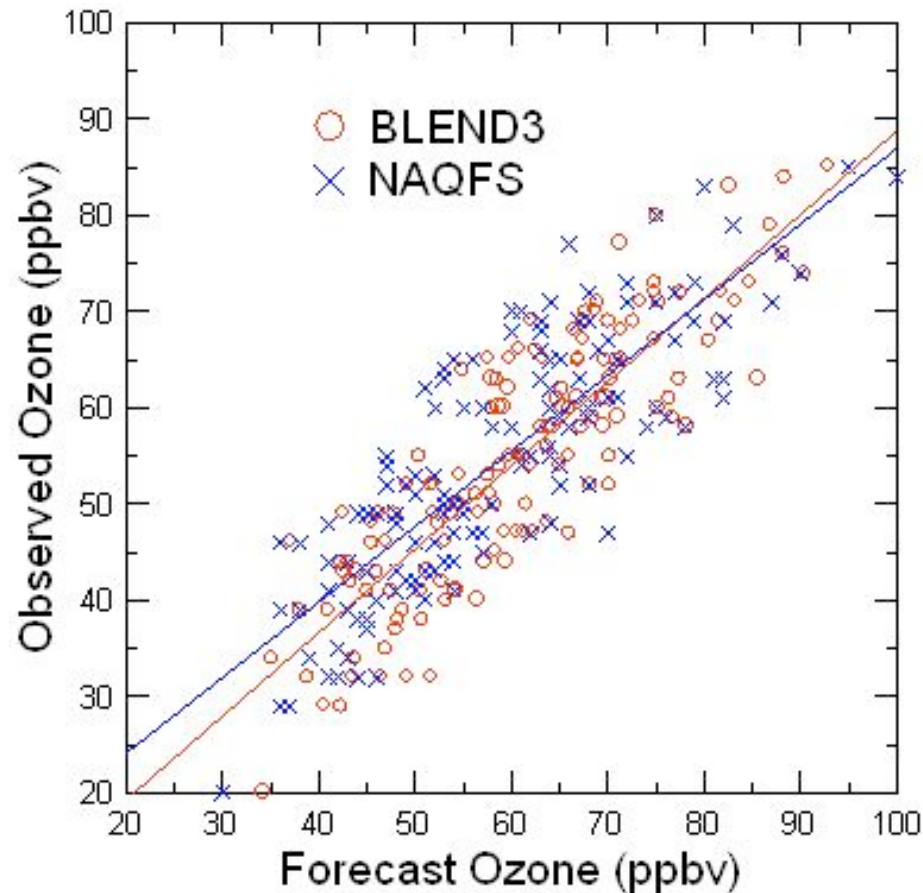

Bias in forecasts of peak domain-wide 8-hour O<sub>3</sub> by two models used in PHL and trained on pre-NO<sub>x</sub> SIP Rule historical data.

# Newest Statistical Model (Trained on Post-NO<sub>x</sub> SIP Rule data) Improves Performance

# Weighted Blend of Statistical and Numerical Models

**2009**

N = 143

**NAQC Blend**

r 0.83 0.85

r<sup>2</sup> 0.68 0.73

NAQFS:

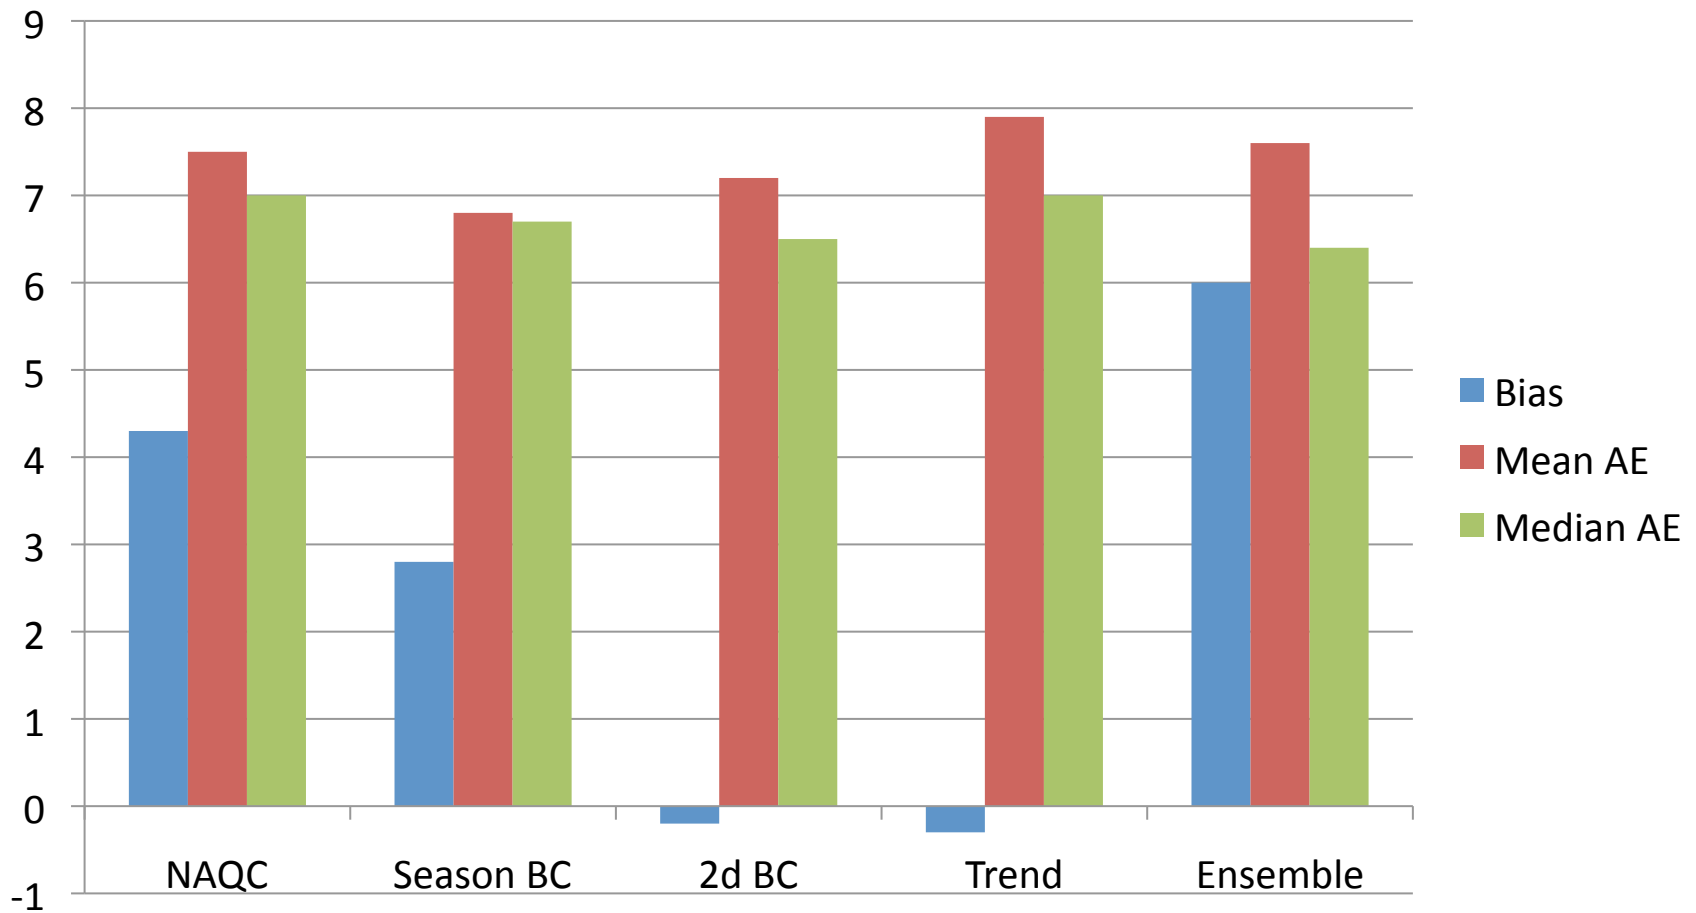

$$[O_3] = 8.5 + 0.78 * [O_3]_{FC}$$

Blend:

$$[O_3] = 2.0 + 0.87 * [O_3]_{FC}$$

Blend 3: 30% R2009 (post-NO<sub>x</sub> SIP), 20% R0302 (pre-NO<sub>x</sub> SIP), 50% NAQFS

# Bias and Absolute Error Statistics for 2009

# Skill Score for Code Orange Threshold (2009)

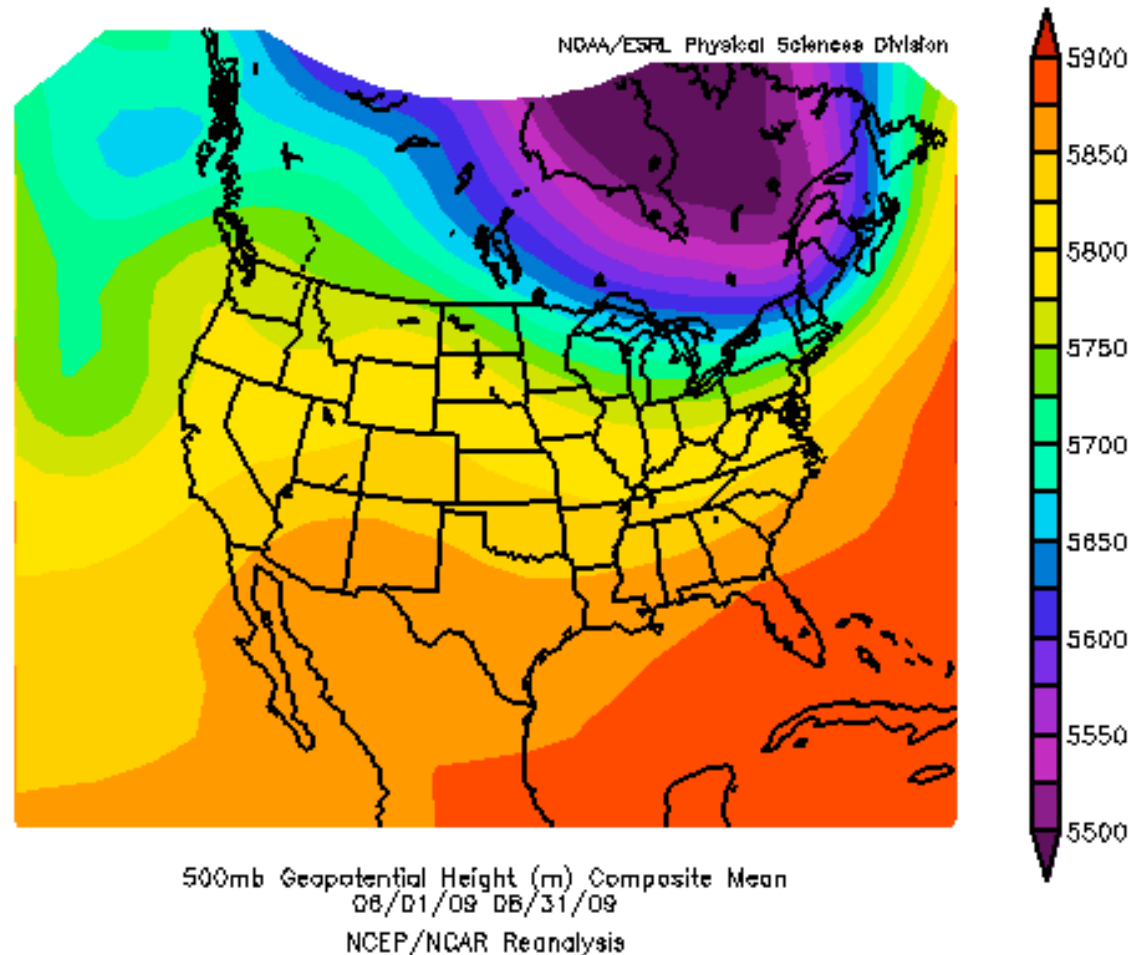

## In Depth Slides: Topic 2

### Comments on the 2009 O<sub>3</sub> Season

- 2009 was a very unusual summer. Low frequency of O<sub>3</sub> conducive weather locally and regionally.
- “Standard” high O<sub>3</sub> weather – westward extension of the Bermuda High, sustained westerly transport from the Ohio River Valley – was infrequent.
- This weather pattern contributed to historically low frequency of high O<sub>3</sub> cases but there may have been lower emissions due to economic recession.

# Mean Summer Upper Air Pattern Featured a Strong and Persistent Area of Low Pressure in Eastern Canada

The northern US was quite cool in June and July with slightly higher than normal precipitation

Temperature Anomalies (F)  
Jun to Jul 2009  
Versus 1971–2000 Longterm Average

Precipitation Anomalies (inches)  
Jun to Jul 2009  
Versus 1971–2000 Longterm Average

## Philadelphia Summer Weather

- Average temperature for MJJA was near normal. However, June and July were 1.5°F below normal.
- August had an average number of hot days ( $\geq 90^\circ\text{F}$ ) but MJJ had only 5 hot days compared to  $\approx 11$  on average.
- All months had more than average number of days with measureable precipitation (17 days in June alone). For the season, 14 additional days of measureable rain ( $\geq 0.01''$ ).
- August was excessively wet with 10.3'' of rain, primarily due to 5 days with  $> 1''$  of rain (average is 1.2 days).

## Weather and Air Quality

- The combination of cooler and wetter than normal weather, and the absence of persistent Bermuda High circulation, led to lower than normal  $O_3$  regionally and locally
  - Shenandoah National Park has historically low frequency of high  $O_3$  days.
  - $PM_{2.5}$  concentrations in PHL very low - pointing to few “dirty” air mass episodes.
  - Almost no high  $O_3$  episodes in Philadelphia.

## Philadelphia: Frequency of High O<sub>3</sub> Days (Peak 8-Hour O<sub>3</sub> in the Metropolitan Area)

# Shenandoah National Park Number of Days with 8-Hour O<sub>3</sub> Above Thresholds

# Shenandoah National Park – Big Meadows Regional Effect of NO<sub>x</sub> Reductions

No days in excess of 70 ppbv in 2009

## PHL PM<sub>2.5</sub> Concentrations Remarkably Low in 2009

Note: Data for 2004-2008 uses gravimetric filter monitors (FRM) while 2009 uses 24-average from continuous monitors.

# Philadelphia: Number of Days with PM<sub>2.5</sub> (Daily Average in $\mu\text{gm}^{-3}$ ) Above Given Threshold

## Shenandoah NP PM<sub>2.5</sub> Daily Average Concentrations (May-August, 2004-2009)

	N	Median (μg/m <sup>3</sup> )	Mean ± 1 σ (μg/m <sup>3</sup> )	Ratio (Days > 20 μg/m <sup>3</sup> )	Ratio (Days > 30μg/m <sup>3</sup> )
2004-2008	487	14.2	15.1 ± 7.8	0.23	0.04
2009	116	9.5	9.8 ± 4.3	0.02	0.00

## In Depth Slides: Topic 3

### Changes in the Temperature-Ozone Relationship

- $O_3$  concentrations are strongly associated with surface temperature ( $T_{max}$ )
- Hot weather is necessary, but not sufficient for high  $O_3$
- Since the implementation of the  $NO_x$  SIP Rule emissions controls, the likelihood of “bad” air given hot temperature has decreased.
- This has impacted the skill of both numerical and statistical forecast models.

# Philadelphia Ozone- Temperature Relationship

Peak 8-Hour  $O_3$  in metropolitan PHL and  $T_{\max}$  (PHL Int'l Airport) for May-Sept, 1993-2009

# Hot Weather is Necessary but not Sufficient for High O<sub>3</sub>

If  $T_{\max}$  is  $\geq 90^{\circ}\text{F}$ , what is the chance of Code Orange ( $\geq 76$  ppbv) or Code Red ( $\geq 96$  ppbv) O<sub>3</sub> occurring?

# O<sub>3</sub> – Temperature Relationship in PHL: NO<sub>x</sub> SIP Rule

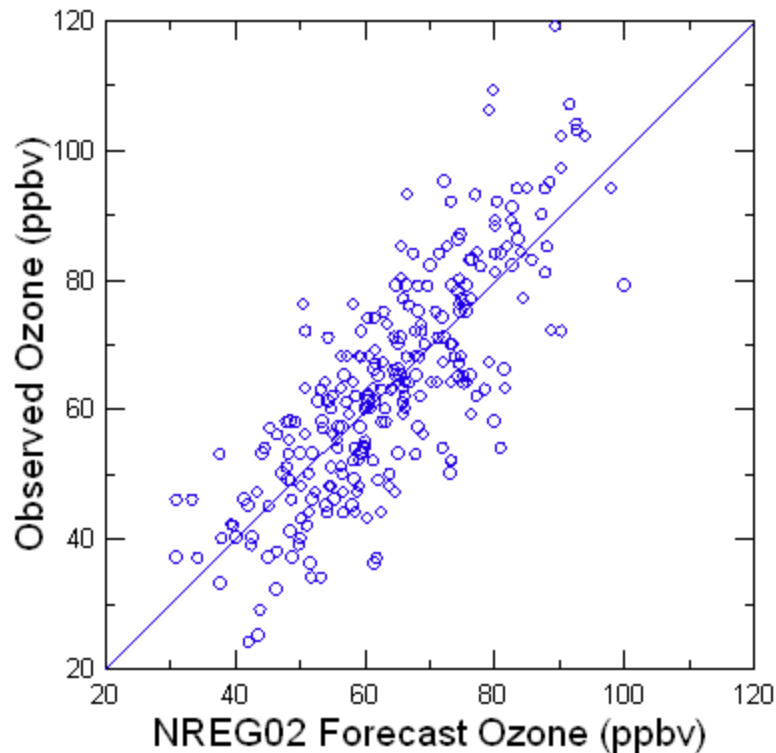

## In Depth Slides: Topic 4

### Using Temperature and Persistence $O_3$ to Post-Process NAQC Guidance

- Using 2007-2008 data, fit observed  $O_3$  and NAQC forecast with two models:
  - NREG01: NAQC and  $T_{\max}$  as predictors
  - NREG02: NAQC,  $T_{\max}$  and  $\text{Lag}O_3$  as predictors
- As applied to 2009 data, both models gave an increase in skill
  - Reduced “false alarms” of high  $O_3$  by two thirds.
  - With no reduction in probability of detection.

# Simple Post-Processing Method

$$[O_3]_{\text{obs}} = f([O_3]_{\text{forecast}}, [O_3]_{\text{persistence}}, T_{\text{max}})$$

**2007-2008**

N = 268

r = 0.79

r<sup>2</sup> = 0.62

$$[O_3]_{\text{obs}} = 0.56 * [O_3]_{\text{NAQC}} + 0.44 * T_{\text{max}} + 0.17 * [O_3]_{\text{lag}} - 20.1$$

Modest improvement in explained variance and correlation

# Fit to Observations in 2009

## Error Statistics – 2009 (all values in ppbv)

	Bias	MedAE	MnAE
NAQC	3.9	7.0	7.4
NREG01	3.1	6.0	6.7
NREG02	2.7	5.9	6.4

Hit Rate unchanged but number of False Alarms reduced from 14 to 5.

3 of 5 False Alarms are “near misses” with observed  $O_3 \geq 71$  ppbv.
